# A critical interpretive synthesis of the roles of midwives in health systems

Cristina A. Mattison<sup>1\*</sup> , John N. Lavis<sup>2</sup>, Michael G. Wilson<sup>2</sup>, Eileen K. Hutton<sup>1</sup> and Michelle L. Dion<sup>3</sup>

## Abstract

**Background:** Midwives' roles in sexual and reproductive health and rights continues to evolve. Understanding the profession's role and how midwives can be integrated into health systems is essential in creating evidence-informed policies. Our objective was to develop a theoretical framework of how political system factors and health systems arrangements influence the roles of midwives within the health system.

**Methods:** A critical interpretive synthesis was used to develop the theoretical framework. A range of electronic bibliographic databases (CINAHL, EMBASE, Global Health database, HealthSTAR, Health Systems Evidence, MEDLINE and Web of Science) was searched through to 14 May 2020 as were policy and health systems-related and midwifery organisation websites. A coding structure was created to guide the data extraction.

**Results:** A total of 4533 unique documents were retrieved through electronic searches, of which 4132 were excluded using explicit criteria, leaving 401 potentially relevant records, in addition to the 29 records that were purposively sampled through grey literature. A total of 100 documents were included in the critical interpretive synthesis. The resulting theoretical framework identified the range of political and health system components that can work together to facilitate the integration of midwifery into health systems or act as barriers that restrict the roles of the profession.

**Conclusions:** Any changes to the roles of midwives in health systems need to take into account the political system where decisions about their integration will be made as well as the nature of the health system in which they are being integrated. The theoretical framework, which can be thought of as a heuristic, identifies the core contextual factors that governments can use to best leverage their position when working to improve sexual and reproductive health and rights.

**Keywords:** Midwifery, Political systems, Health systems, Critical interpretive synthesis, Sexual and reproductive health and rights

## Introduction

Midwives' roles in sexual and reproductive health and rights (SRHR) continue to evolve and an understanding of the profession's role in health systems is essential in creating evidence-informed policies. Countries across all income levels face challenges with providing high-quality SRHR and achieving effective coverage [1]. National or sub-national SRHR policies often do not include the

midwifery workforce or account for the professions' role in the provision of high-quality care [1]. The lack of conceptual clarity regarding the drivers of midwives' roles within health systems, ranging from their regulation and scope of practice to their involvement in care, has resulted in significant variability both within and across countries on how the profession is integrated into health systems.

Research on midwifery care has demonstrated that the profession delivers high-quality SRHR services [1–3]. Care provided by midwives who are trained, licensed and regulated according to international standards is

associated with improved health outcomes [3–7]. While midwifery care is associated with positive outcomes, it is an area that is under-researched [8]. This is particularly true in relation to how political and health system factors influence the profession's role in health systems. As such, the roles of midwives in health systems are not clearly understood, which continues to challenge the profession's ability to work effectively in collaborative and interprofessional settings.

Midwifery research is often dichotomised by the development status of the jurisdiction of focus — high-income countries (HICs) compared to low- and middle-income countries (LMICs). In HICs in general, midwives' roles are focused on primary care to low-risk pregnant people through pregnancy, labour and a limited post-partum period [9]. In comparison, in LMICs, midwives' scope of practice can be broader and extends to many aspects of SRHR [10–13]. International organisations (e.g. WHO, United Nations Population Fund and the International Confederation of Midwives) support an expanded approach to midwifery roles to include provision of a range of SRHR services (e.g. health counselling and education, prevention of mother-to-child HIV transmission, prevention and treatment of sexually transmitted infections, and provision of safe abortion where legal) [4, 14].

Arguably one of the most crucial components of a health system is its health workforce, as highlighted by WHO's framework of 'building blocks' to support health systems strengthening (service delivery, health workforce, health information systems, access to essential medicines, financing and governance) [15]. While midwifery is recognised as key to SRHR, there is a global shortage of the midwifery workforce [2, 4]. Midwives who are educated and regulated according to international standards can provide 87% of a population's essential SRHR, yet only 36% of the midwifery workforce is made up of such fully trained midwives, with a range of other health workers also delivering midwifery services [4]. The latter has been made possible by the range of roles that non-midwife health workers play in providing midwifery services [4, 16].

The lack of understanding of the roles of midwifery in health systems has led to significant disparities within and across countries. A better understanding of the roles of midwives within the health system is desirable as they are a key component in the delivery of safe and effective SRHR and could possibly improve the cost-effectiveness of the delivery of these services [17–19]. There is growing recognition that, to strengthen health systems, decisions must be based on the best available research evidence [20–23]. Using the available research evidence to understand the roles of midwives across health systems, as well as the political and health system drivers, will yield important insights with the aim of adding to the evidence base that policy-makers can draw from.

The present study asks — across health systems, what are the factors that influence the roles of midwives within the health system? We present a theoretical framework to explain how political and health system factors influence the roles of midwives within the health system. It defines the political system as consisting of three main components, namely institutions, interests and ideas [24]. 'Health system arrangements' are made up of governance, financial and delivery arrangements, and implementation strategies [25]. Given the lack of theoretical development in the area, this paper, through a critical interpretive synthesis of the available literature, identifies the factors that act as barriers or facilitators to the roles of midwives.

## Methods

### Design

A critical interpretive synthesis was used to develop the theoretical framework, which is an inductive approach to literature analysis. The approach uses conventional systematic review processes while incorporating qualitative inquiries to examine both the empirical and non-empirical literature [22]. Critical interpretive syntheses are best suited to developing theoretical frameworks that draw on a wide range of relevant sources and are particularly useful when there is a diverse body of literature that is not clearly defined, as is the case with literature related to the roles of midwives in health systems. Conventional systematic reviews have well formulated research questions at the outset, while a critical interpretive synthesis employs a compass question, which is highly iterative and responsive to the findings generated in the review process [26].

### Literature search

The selection of the literature was carried out in phases (Fig. 1). The first phase consisted of a systematic search of electronic bibliographic databases. The searches were executed in consultation with a librarian, who provided guidance on developing keywords (along with Boolean operators) and MeSH (Medical Subject Heading), refining the search strategy, identifying additional databases and executing the searches. We searched the following electronic databases through to 14 May 2020: CINAHL, EMBASE, Global Health database, HealthSTAR, Health Systems Evidence, MEDLINE and Web of Science. The search strategy was first developed in the MEDLINE database, using keywords and MeSH. Similar search strings were used across databases, with minor adjustments made to ensure search optimisation. The searches in MEDLINE included *midwi\** AND (roles OR scope), *midwi\** AND delivery of health care (MeSH), *midwi\** AND patient satisfaction (MeSH), *midwi\** AND quality

of health care (MeSH), and midwi\* AND standards (MeSH).

The second phase, complementary to the bibliographic database search, was a search of policy and health systems-related SRHR and midwifery organisation websites for relevant documents (e.g. World Health Assembly resolutions and United Nations Population Fund's State of the World's Midwifery reports). In addition, hand searches of reference lists from key publications were used to identify further relevant literature (e.g. 2014 *Lancet* Series on Midwifery). The final step in the literature search process was a purposive search to identify literature to fill the conceptual gaps that emerged.

#### Article selection

For inclusion, the documents had to relate specifically to trained midwives, with leeway in terms of title (e.g. certified nurse-midwives and certified midwives in the United States). Articles were included, that in addition to providing insight into the compass question, also (1) incorporated a range of perspectives across different countries; (2) integrated different concepts into one document; and (3) included perspectives on the compass question from other disciplines (e.g. geographic information system and other techniques to map the distribution of the midwifery workforce). In order to incorporate a broad range of documents, there were no

limits placed on the searches such as regarding language or publication year.

An explicit set of exclusion criteria were developed by the research team to remove the documents that were not relevant to the aims of the study and did not link to the compass question. Exclusion criteria included documents (1) with a clinical focus (e.g. clinical guidelines, pharmacology, diagnostics, devices, surgery and/or treatment of shoulder dystocia, diabetes, hypertensive disorders, in pregnancy), unless the focus was on scope of practice (e.g. midwives working in expanded scopes); (2) focused on models of care that were specific to individual practices or hospitals and included those that were related to health system approaches; (3) relating to unskilled workers providing SRHR (e.g. traditional birth attendants); (4) focused on implementation of a programme or evaluation of the programme (e.g. prenatal and postnatal programmes), unless the focus was on the roles of midwives providing care within the health system; (5) focused on midwifery education, unless the focus was on accreditation, training and licensure requirements; and (6) focused on site of service delivery (e.g. outcomes of hospital and home births), unless the focus was on the roles of midwives within the different practice settings.

Once the series of searches were completed, an Endnote database was created to store and manage the results. All the duplicates were removed from the database and an initial review of the titles and abstracts was

performed for each entry by the principal investigator (CAM) and records were classified as ‘possibly include’ or ‘exclude’. In the first stage of screening, records were marked as ‘possibly include’ if they provided insight into the study’s compass question. Full-text copies of the remaining records were retrieved and uploaded to Covidence, an online tool for systematic reviews, for final screening [27].

The last stage of screening involved two phases and consisted of full-text review by three reviewers (CAM, TD and KMB). Using Covidence, each reviewer examined the records independently to assess inclusion. Any discrepancies were discussed and resolved. The reviewers prioritised the inclusion of empirical articles where possible, including empirical qualitative studies, which are the types of articles most likely to address political and health system components.

### Data analysis and synthesis

A coding structure was created to guide the data extraction. The areas of expertise of the authors (health systems and policy, clinical practice and political science) informed the selection of frameworks guiding the data extraction. The political system factors were informed through the 3i framework, which is a broad typology that recognises the complex interplay among institutions, interests, and ideas and provides a way of organising the many factors that can influence policy choices [24, 28–30]. Institutions are made up of government structures (e.g. federal versus unitary government), policy legacies (e.g. the roles of past policies) and policy networks (e.g. relationships between actors around a policy issue). Interests can include a range of actors who may face (concentrated or diffuse) benefits and costs with particular courses of action, whereas ideas relate to peoples’ beliefs (including those based on research evidence) and values.

‘Health system arrangements’ were informed through an established taxonomy developed by the McMaster Health Forum that includes (1) governance arrangements (e.g. policy authority, organisational authority and professional authority); (2) financial arrangements (e.g. how systems are financed and health professionals remunerated); (3) delivery arrangements (e.g. how care meets consumers’ needs, who provides the care and where it is provided); and (4) implementation strategy (consumer- or provider-targeted strategies) [25]. The components of the framework for quality maternal and newborn care (practice categories, organisation of care, values, philosophy and health professionals) were incorporated into the health system arrangements coding structure to yield insights specific to midwifery care [3].

In addition to the frameworks that guided data extraction, further data was collected on publication year, study design and jurisdiction(s) of focus. A data extraction form was developed based on all of the concepts covered in the frameworks as well as the additional descriptive items.

The critical interpretive synthesis was conducted on the high value articles — those that yielded the most insight into the compass question. The reviewers prioritised the inclusion of empirical articles that were conceptually rich or integrated different concepts, filled disciplinary gaps, captured a breadth of perspectives across different countries or applied approaches outside of health. The articles were read by the principal investigator (CAM) and one- or two-page detailed summaries were created for each article. The summaries were coded using the qualitative software NVivo for Mac, which facilitates the organisation and coding of the data [31]. Coding was informed by the three key frameworks guiding the analysis and outlined above: 3i framework, ‘health system arrangements’ and components of the framework for quality maternal and newborn care.

Three steps were involved in the analysis for the critical interpretive synthesis. First, the summaries of the articles were coded based on the coding structure outlined in the data extraction form. Using a constant comparative method, emerging data were compared to previously collected data to find similarities and differences [32, 33]. The approach included observations on the terms and concepts used to describe midwifery within the health system as well as relationships between the concepts. For example, how the role of midwives within the health system is influenced by policy legacies (i.e. institutions), which is related to problems with collaborative/interprofessional environments (i.e. delivery arrangements, skill mix and interprofessional teams). Second, all the data collected under each code was reviewed and more detailed notes of the concepts that emerged were included in the analysis. Lastly, themes were created for the concepts that emerged throughout the analysis.

Completeness of the findings was ensured through ongoing consultation with members of the research team. Central concepts and emerging themes of the study were discussed as a team and applied to current scholarship within the field of health systems and policy.

## Results

### Search results and article selection

A total of 7779 records were identified through the searches of electronic bibliographic databases. Once duplicates were removed ( $n = 3246$ ), the remaining records ( $n = 4533$ ) were screened based on title, abstract and the explicit set of exclusion criteria outlined above, leaving 401 potentially relevant records. In addition to the

electronic database search, 29 records were purposively sampled for inclusion through grey literature and hand searches. The remaining 401 documents from the electronic database searches and 29 documents from the grey literature and hand searches were assessed by the reviewers (CAM, TD and KMB) for inclusion using the full text. A total of 100 documents were included in the critical interpretive synthesis (Fig. 1).

Over three-quarters (79%) of the documents were published after 2010, with no documents published prior to 2000. Of the 100 documents, the majority were primary research ( $n = 78$ ), which were mostly qualitative research ( $n = 24$ ) and observational studies ( $n = 24$ ), followed by the 'other' category ( $n = 18$ ) (e.g. geographic information systems research), systematic reviews ( $n = 15$ ) and mixed methods ( $n = 4$ ), while 1 was a randomised control trial. The remaining documents were categorised as non-research ( $n = 22$ ), meaning that the approaches taken in the documents were either not systematic or that the methods were not reported transparently. Of the non-research documents, 8 were theoretical papers, 7 were reviews (non-systematic), 4 were 'other' (e.g. World Health Assembly resolutions, toolkits, etc.), and the remaining 3 were editorials. Forty-one of the documents focused on LMIC settings, followed by 35 on HIC settings, and 24 focused on both HIC and LMIC settings.

The results of the critical interpretive synthesis focused on the political and health system factors that influenced the roles of midwives within health systems. Table 1 focuses on the political system factors that emerged from the analysis and presents the relevant themes, relationships with other factors, and key examples from the literature of the factors that acted as either barriers or facilitators to the roles of midwives within the health system. Similarly, Table 2 focuses on the health system factors and presents the relevant themes, relationships with other factors, and key examples from the literature on the 'health system arrangements' that either acted as barriers or facilitators to the roles of midwives.

Three main findings emerged from the analysis on political system factors. First, within institutions, the effects of past policies regarding the value of midwives created interpretive effects, shaping the way midwifery care is organised in the health system. The legacies of these policies created barriers, which include SRHR policies that reinforced structural gender inequalities as well as, in a medical model, payment systems privileging physician-provided and hospital-based services [11, 13, 34, 41–45, 47–52, 54–59, 61–63, 65].

Second, interest groups played an important role in either supporting or opposing the integration of midwifery in the health system. These groups can have direct or indirect influence and policies that provide

concentrated benefits and diffuse costs for groups are more likely to move forward [24]. Interest groups advanced the integration of midwifery in the health system by (1) creating partnerships to improve SRHR [45, 67]; (2) promoting regulation and accreditation (e.g. accreditation requirements, setting standards, policies and guidelines) [63, 68–70]; (3) capacity-building including midwifery research [71, 72]; (4) policy leadership and decision-making [43]; and (5) lobbying governments and advocacy [73, 74]. Strong leadership from midwifery professional associations engaged in policy dialogue and decision-making has helped advance agendas related to universal health coverage and meeting health-related United Nations Sustainable Development Goals [8, 63, 66, 71, 90].

Third, the most relevant themes related to ideas that emerged from the analysis pertained to societal values regarding gender (women's roles within society) as well as the medical model (historical medicalisation of the birth process and associated growth of physician-provided and hospital-based care). We recognise the importance of gender-inclusive language but have used the term 'women' in this publication to reflect how gender is referenced in the documents reviewed. Barriers created by societal values included (1) social construction of gender and the status of midwives in a given jurisdiction often reflected the value placed on women within society (i.e. 'gender penalty') [8, 11, 41, 43, 46, 48, 61, 71]; (2) some cultures and beliefs did not allow women to receive care from men, yet there were few health professionals who were women due to lack of educational opportunities and societal values that restrict women from participating in the paid labour force [45]; and (3) health system priorities and shifting societal values favoured the medical model [41, 48–50, 75, 78, 99–101]. Examples of facilitators included Nordic health systems that value non-medical models and women-dominated professional groups [37], which respect the right to informed choice [86].

Within health system factors, the main themes that emerged from the literature are presented according to 'health system arrangements'. First, within governance arrangements, regulation and accreditation mechanisms to support midwifery education programmes and institutional capacities were central to how midwives are integrated into health systems [63, 70, 93, 107]. The lack of legislation to support regulatory activities [34, 43, 48, 58, 71, 82, 87, 93, 94] limited recognition and scope [38, 87] and the ability for midwives to practice as an autonomous profession [80]. Globally, there was a general lack of knowledge regarding the International Confederation of Midwives' Global Standards for Midwifery Education, which was a barrier to the provision of quality midwifery education [53, 66, 87, 107, 108]. Within financial arrangements, the literature focused primarily on how systems are financed, on the inclusion of midwifery services within financing systems and on the remuneration of

midwives that is reflective of scope of practice [1, 2, 6, 10, 13, 35, 38, 39, 43, 50, 55–59, 61, 69, 73, 74, 76, 80, 84, 95, 101, 104, 109, 115]. Lastly, the main themes relating to delivery arrangements focused on (1) accessing midwifery care ranging from availability and timely access to workforce supply, distribution and retention; (2) by whom care is provided (e.g. task-sharing and inter-professional teams); and (3) where care is provided (e.g. hospital-based, integration of services and continuity of care) [3, 4, 6, 7, 9–13, 34–39, 43, 45, 46, 48, 50, 51, 54, 55, 58, 59, 61, 62, 69, 73, 74, 76, 77, 79, 86, 94, 96, 97, 99, 100, 104, 105, 110, 116–118, 120–122].

### Theoretical framework

Figure 2 brings together the main findings from the critical interpretive synthesis and presents a theoretical framework, which can be thought of as a heuristic that can be used to map the key elements that influence midwives' roles in a particular political and health system. The factors presented in the framework are not weighted but rather present the range of variables influencing the level of integration of the profession. The cumulative effects of the barriers presented on the right-hand side of the framework lead to health systems where the profession is disempowered and midwives exist on the margins with very limited capacity. Some of the variables and examples presented in the framework have context specificity to reflect findings from the critical interpretive synthesis (e.g. self-regulated profession, Indigenous self-government, Nordic maternity care systems, and payment systems privileging physician-provided and hospital-based services in some contexts).

## Discussion

### Principal findings

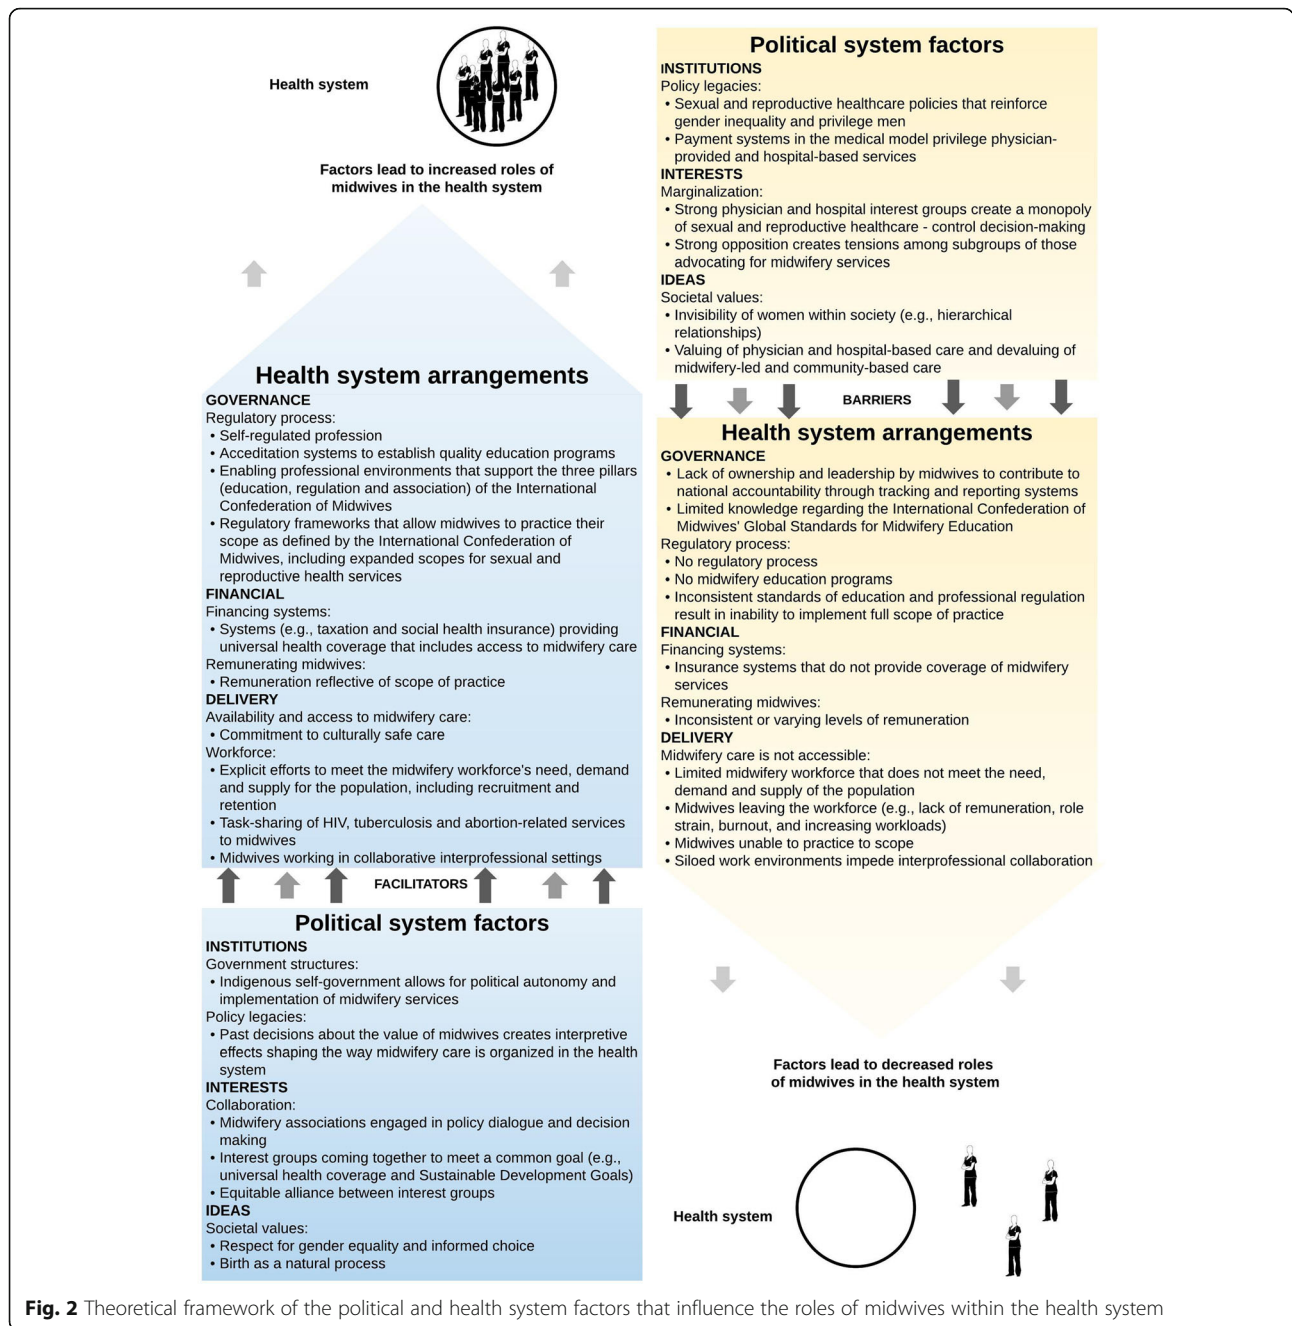

Similar to the concept of WHO's health system 'building blocks', the political system factors presented in the theoretical framework form the bottom building block or the foundation for the 'health system arrangements', acting as either a barrier or facilitator. For example,

favourable institutional factors (e.g. policy legacies that value midwifery as a profession), interests (e.g. collaborative interest groups coming together to reach a common goal) and ideas (e.g. societal values centring on gender equality and birth as a natural process) act as enablers to 'health system arrangements' that build on each other to support the integration of midwifery. Together, supportive political and health system factors lead to health systems where midwives practice to scope (i.e. trained, licensed and regulated according to international standards, working in collaborative/interprofessional settings with an established workforce). On the other hand, health systems that have many political and health system challenges will in turn have a limited midwifery workforce where midwives lack an institutional voice and representation in SRHR decision-making. Significant barriers limit the options available to the midwifery workforce and is most often reflected in siloed work settings with midwives working in the periphery of the health system.

### Strengths and limitations of the study

The main strength of the study is the use of a critical interpretive synthesis. This is a relatively new systematic review methodology, which combines a rigorous systematic review of electronic bibliographic databases with iterative and purposive sampling of the literature to fill conceptual gaps. The approach incorporated a range of documents (empirical and non-empirical), which broadened the scope of the literature used to inform the theoretical framework.

The main limitation of the critical interpretive synthesis was that the search strategy may not have fully covered the diverse terminology used to refer to midwifery. However, the principal investigator (CAM) consulted with a librarian and team members to ensure that the search strategy was as inclusive as possible, which is also reflected by the high proportion of articles that were later excluded during the screening process. Meanwhile, the majority of articles retrieved from the searches were

**Fig. 2** Theoretical framework of the political and health system factors that influence the roles of midwives within the health system

published after 2000, which could be related to the release of the Millennium Development Goals and subsequent Sustainable Development Goals, and the wider attention given to SRHR on global agendas.

### Implications for policy and practice

Any changes to the roles of midwifery in health systems needs to take into account the political system where decisions about their integration will be made as well as the nature of the health system in which they are being integrated. The theoretical framework is a tool that helps

to inform such changes by identifying the drivers of midwives' roles that facilitate or constrain such integration. The study results have implications for policy-makers as, firstly, the theoretical framework can be used to conduct an assessment of the factors in order to strengthen the profession by identifying the facilitators that can be leveraged as well as the barriers that can be addressed to support change. For example, Sweden has favourable political system conditions (e.g. policy legacies of professionalisation of midwives dating back to the eighteenth century and an equitable alliance between

midwifery and physician groups), which is reflected in the health system arrangements where midwives are the primary health professionals for low-risk pregnant people. In contrast, the United States has policy legacies of payment systems valuing physician-provided and hospital-based care, strong physician and hospital interest groups have created a monopoly over sexual and reproductive health services, and existing tensions within the profession between nurse midwives and midwives.

Moving forward, an implication for practice is that changes to further enhance the role of midwives would require different types of policy levers. In looking at growing midwifery in LMICs, governments can use the tool to understand how to best influence the integration of the profession. This information will provide valuable experience and understanding of the contextual factors so that governments can best leverage their position when working with bilateral and multilateral funders to improve SRHR. Conversely, in the example of the United States, the framework presented helps to explain why midwives play such a small role in sexual and reproductive health service delivery in the United States. The tool highlights that funding and regulatory levers would need to be pulled; yet, strong policy legacies and entrenched interests present significant barriers. Change would require spending political capital to modify existing structures within the health system.

## Conclusions

While research evidence on the role of midwives in the provision of high-quality SRHR has increased and the 2014 *Lancet* Series on Midwifery was key to raising the profile of midwifery research, significant gaps in the literature persist. Structural gender inequalities are reflected in the low status of midwifery in some contexts, which leads to poor political and health systems supports to invest in quality midwifery care [43]. Our findings show that the research evidence related to the roles of midwives within health systems is relatively saturated in terms of delivery arrangements yet surprisingly little is known about governance and financial arrangements and about implementation strategies, which are key to effectively integrating midwifery and pushing the field forward in meaningful ways.

## Abbreviations

HICs: High-income countries; LMICs: Low- and middle-income countries; SRHR : Sexual and reproductive health and rights

## Acknowledgements

The authors would like to thank Kirsty Bourret and Tomasso D'Ovidio for their assistance with assessing documents for eligibility and inclusion in the review.

## Authors' contributions

CAM conceived the study design with her supervisor, JNL, and was responsible for all data collection and analysis. JNL, EKH, MGW and MLD

provided content expertise (health systems and health policy, clinical practice and political science) to inform the selection of frameworks guiding the data extraction. All authors contributed to the development of the conceptual framework and approved the final manuscript.

## Funding

There are no sources of funding to declare for this research.

## Availability of data and materials

All data generated or analysed during this study are included in this published article and summarised in Tables 1 and 2.

## Ethics approval and consent to participate

Not applicable.

## Consent for publication

Not applicable.

## Competing interests

The authors declare that they have no competing interests.

## Publisher's Note

Springer Nature remains neutral with regard to jurisdictional claims in published maps and institutional affiliations.

**Ready to submit your research? Choose BMC and benefit from:**

- fast, convenient online submission
- thorough peer review by experienced researchers in your field
- rapid publication on acceptance
- support for research data, including large and complex data types
- gold Open Access which fosters wider collaboration and increased citations
- maximum visibility for your research: over 100M website views per year

**At BMC, research is always in progress.**
